

Module 3- Periodic Table and Atomic Models

1. ATOMIC NUMBER AND MASS NUMBER

Rutherford discovered that the atom consisted of a nucleus which contains protons and neutrons. The electrons orbit around the nucleus.

Protons and neutrons have roughly the same mass, and each is about 2000 times as massive as the electron. Therefore we can say that most of the mass of the atom is located in the nucleus.

Facts about atom:

- The number of protons is the same as the number of electrons.
- For any given element, all nuclei have the same number of protons, but the number of neutrons may vary.
- The charge on the electron is $-e$. The charge on the proton is $+e$.
- The charge on the neutron is zero.

Remember: The elementary unit of charge is $e = 1.602 \times 10^{-19} \text{ C}$.

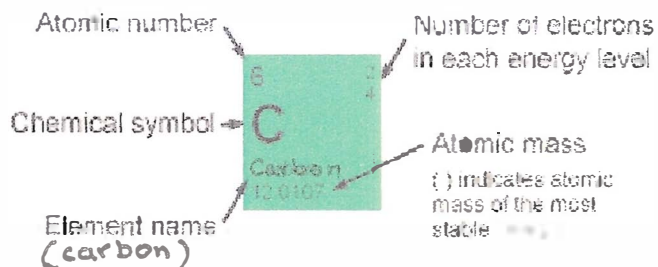

— **Atomic Number** is the number of protons in the nucleus, which is the same as the number of electrons in a neutral atom.

— **Mass Number** is the total number of neutrons and protons in the nucleus which is equal to the approximate mass of the atom to the nearest integer. (In fact the atomic mass is the sum of the masses of all the atom's components i.e., electrons, protons, and neutrons. As the electron's mass is too small, we may treat their contribution to the atomic mass as negligible.)

2. PERIODIC TABLE

The Periodic table is a listing of all known elements with their chemical symbols, atomic numbers, and atomic masses along with other information as shown in the table on page 3.

The way the table is organized in groups tells us a lot about these elements' structure and their properties. The on the right provides a key to read and understand the periodic table. Each horizontal row is called a **period** and each vertical column is called a **group**.

Periodic Table of the Elements

3. THE STRUCTURE OF THE ATOM

Earlier model

The atom was once thought to be a solid ball of positive material with pudding-like consistency with electrons placed as shown in the figure. The atom was supposed to be of a uniform density.

This was an incorrect model of the atom.

Rutherford Model

Ernest Rutherford was the first to show that the atom does not have a uniform density, and that most of its mass is located at its center.

Based on his alpha-particle scattering experiment on gold, Rutherford concluded that the atom consisted of a hard central core where most of the mass of the atom is present.

Ernest Rutherford won 1908 Nobel Prize for studies in radioactivity.

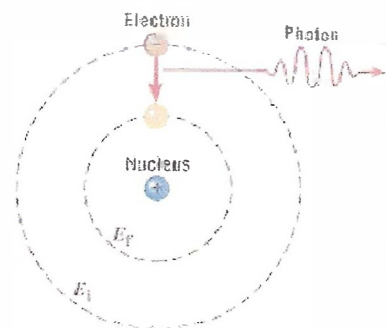

Bohr's model

Neils Bohr, a Danish physicist, treated the hydrogen atom as if it were an electron of charge $-e$ orbiting in a circular path about a proton of charge $+e$.

Energy levels in hydrogen

Bohr also suggested that the electrons may reside in various energy levels of the atom. Three such levels are shown in the figure. In this figure " n " is the **principle quantum number** which is always an integer. $n = 1$ is the ground state, $n = 2$ is the 2nd energy level, $n = 3$ is the 3rd energy level, and so on. The electron can undergo a transition from a lower to higher or from a higher to lower energy level.

Energy transitions in atoms

When an atom absorbs some energy the electron can jump to a higher energy level. But the electron cannot stay in this energetic state for a long time and it will fall back to its original energy level after emitting light. This light consists of discrete particles called "**photons**". For such transitions we can say that:

- (i) Energy of photon = Energy lost by electron
- (ii) The energy of the emitted photon is equal to the difference in energy between the two levels involved in the transition.

4. RADIOACTIVITY

Radioactivity is a process by which certain elements (with unstable nuclei, e.g., U_{238} , C_{14} , etc.) emit particular forms of radiation and decay into another element.

There are three major forms of radiations known as *alpha*, (α) *beta* (β), and *gamma* (γ) radiation.

The first particle/radiation discovered in such a decaying process of an unstable nucleus was called an alpha particle because alpha is the first letter of the Greek alphabet.

An element that emits any of these forms of radiation is called a **radioactive element**.

Alpha emission

U_{238} emits an alpha-particle and decays into Th_{234} element as shown. Alpha particle consists of two protons and two neutrons, which is the same as a helium nucleus.

Beta emission

C_{14} emits a beta-particle and decays into N_{14} element as shown. The beta particle is just an electron.

Gamma emission

Nuclei with excess energy emit gamma-rays which have extremely short-wavelength (very high energy $E = h\nu$) electromagnetic waves or photons.

Blocking radiation

Alpha particles are 8,000 times as heavy as beta particles.

Paper or clothing can easily block alpha particles, while beta particles require a few sheets of aluminum foil.

Gamma radiations are extremely dangerous, a thousand times more dangerous than x-rays. They can easily penetrate most of the material except materials that are extremely dense such as lead (Pb). Thick lead slabs are normally used to block gamma radiations in hospitals, nuclear plants etc. to minimize their harmful effects.
